Overview: CPU Registers

Register are the “variables” on the CPU

Immediate access for the CPU

Cannot write Memory -> Memory

★ Always: Memory -> Register -> Memory

Register: <1 cycle

L1: ~3

L2: ~14

RAM: ~240

Overview: CPU Registers

Registers are of a certain size

- ★ e.g. 64 bit (can hold a number of size 8 bytes)

Register can hold:

- ★ Data (numbers)
- ★ Addresses (also numbers, but with a different meaning)

Registers can be used to:

- ★ Perform computations(add, multiply, xor..)
- ★ Read / Write memory(address in register)
- ★ Execute instructions(special registers)

Overview: CPU Registers

32	64	Acronym	What?
EAX	RAX	Accumulator	Adding stuff
EBX	RBX	Base	Referencing stuff
ECX	RCX	Count	Counting stuff
EDX	RDX	Data	Stuff
ESI	RSI	Source Index	Points to a source
EDI	RDI	Destination Index	Points to a destination
	R8-R15		General Purpose

Overview: CPU Registers

32	64	Acronym	Points to?
EIP	RIP	Instruction Pointer	Next instruction to be executed
ESP	RSP	Stack Pointer	Top of Stack
EBP	RBP	Base Pointer	Current Stack Frame (Bottom)

Fun Fact: Current Intel CPU's are compatible to the 8086

8086:

- ✦ From 1978
- ✦ 5-10mhz

Overview: CPU Registers

Recap:

- ★ CPU work with **registers**
- ★ Registers can hold **data**
- ★ Registers can also hold **addresses** of memory locations (to write/read data)
- ★ They can be 32 bit (**EAX**) or 64 bit (**RAX**)
- ★ Some registers are multi-purpose
- ★ Some registers are special (RIP, RBP, RSP)

How a CPU interprets instructions

CPU Instructions

A CPU in a few lines of code:

```
instr = [ 0x01 0xA0 0xB0 0x02 0xA1 0xA2 .. ]
```

```
ip = 0
```

```
while true:
```

```
    switch instr[ip]:
```

```
        case 0x01:
```

```
            add( instr[ip+1], instr[ip+2] )
```

```
            ip = ip + 3
```

```
            break
```

```
        case 0x02:
```

```
            sub( instr[ip+1], instr[ip+2] )
```

```
    ...
```

Description

Adds the first operand (destination operand) and the second operand (source operand) and stores the result in the destination operand. The destination operand can be a register or a memory location; the source operand can be an immediate, a register, or a memory location. (However, two memory operands cannot be used in one instruction.) When an immediate value is used as an operand, it is sign-extended to the length of the destination operand format.

The ADD instruction performs integer addition. It evaluates the result for both signed and unsigned integer operands and sets the OF and CF flags to indicate a carry (overflow) in the signed or unsigned result, respectively. The SF flag indicates the sign of the signed result.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

Operation

$\text{Destination} = \text{Destination} + \text{Source};$

Numbers in memory

Recap:

- ✦ Numbers can be displayed in decimal, or hex (0-9, a-f)
- ✦ Numbers are stored as 16, 32 or 64 bit values, mostly as little endian
- ✦ If we look at little endian numbers as bytes, they are inverted
- ✦ If we look at numbers in memory, we can't know if they are 8, 16, 32 or 64 bit
- ✦ We can try to interpret bytes as ASCII

Numbers test!

$0x07 + 0x07 = ?$

$0x0a + 0x0a = ?$

$0x22 - 0x10 = ?$

$0x22 - 0x0a = ?$

$0xbb4c00d$ in little endian = $0x????????$

ASCII $0x42$ $0x46$ $0x48$ = «???»

The string «leet» in ASCII = $0x??$ $0x??$ $0x??$ $0x??$

Operating System Basics

OS Basics: Rings

Ring 0: Kernel (Kernelspace)

- ✦ Not covered here
- ✦ Can be interacted with by using “syscalls”

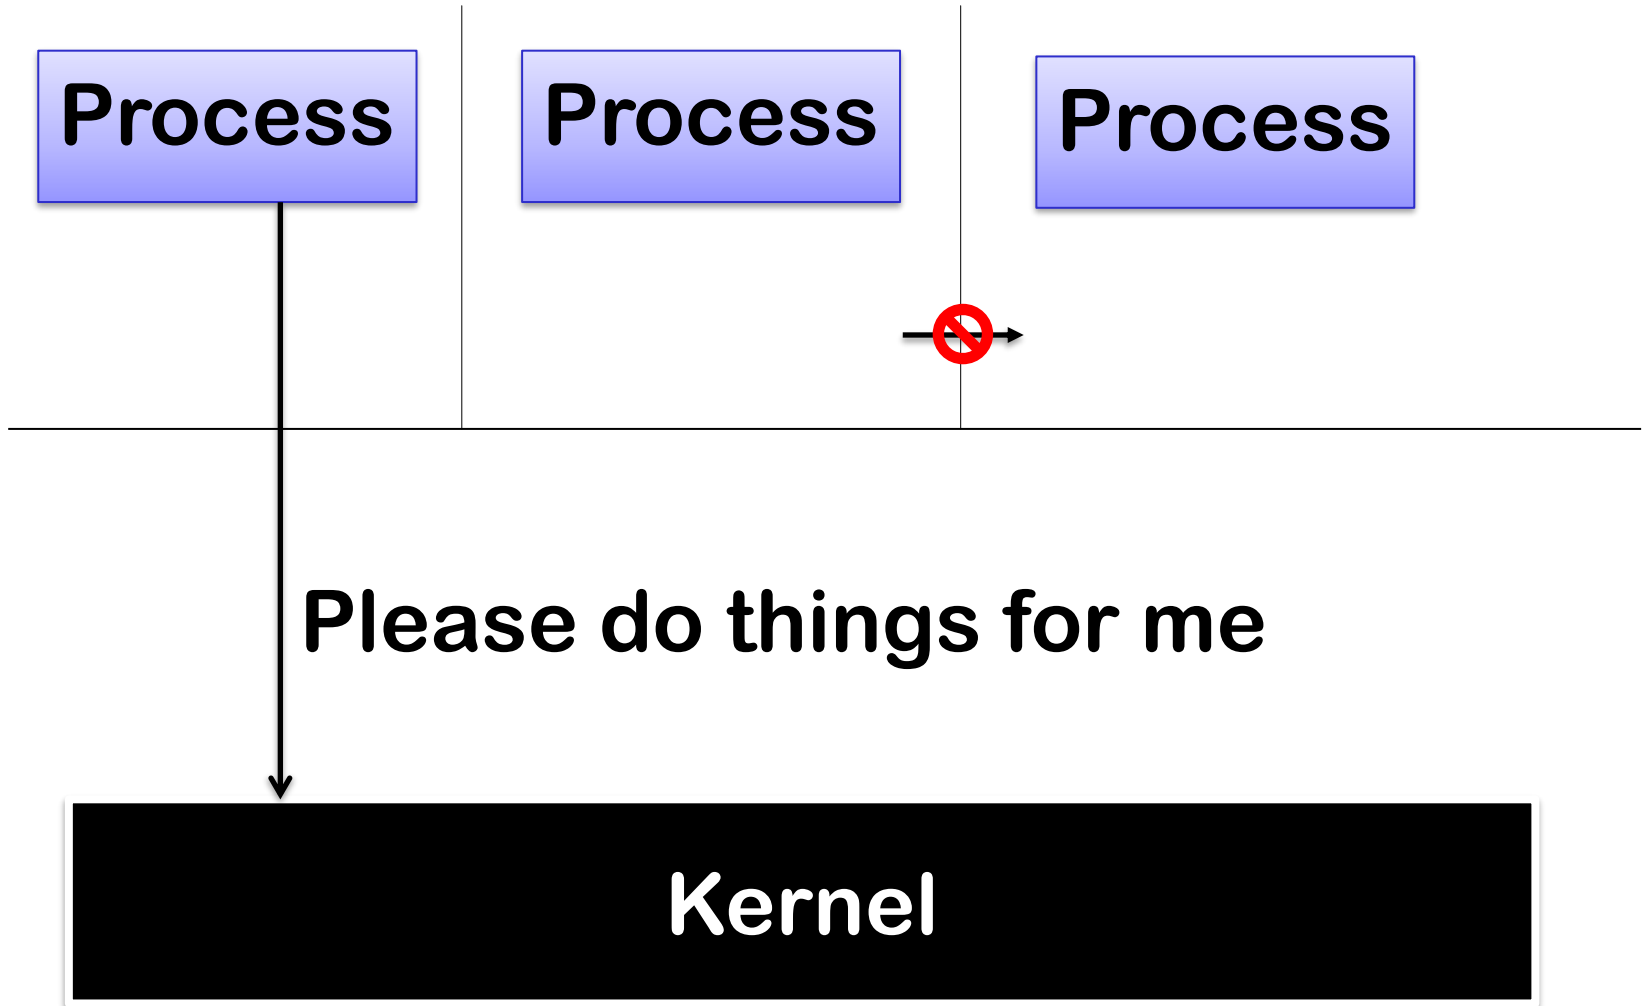

Ring 3: Userspace

- ✦ Where all programs run
- ✦ ls, Bash, Vim, Apache, Xorg, Firefox, ...

How to transit from userspace to kernelspace?

- ✦ System Calls (syscall)

A Process:

- ✦ Is a **running** program
 - ✦ Program lives on disk (static, dead)
 - ✦ Process lives in memory (interpreted, alive)
- ✦ Process thinks he “owns” the hardware
 - ✦ RAM
 - ✦ CPU

Multiple processes can run simultaneously

- ✦ Everyone thinks he is the only one
- ✦ Like Kanye West

OS Basics: Processes

A Process:

- ✦ Is a *running* program
 - ✦ Program lives on disk (static)
 - ✦ Process lives on memory (alive)
- ✦ Process thinks he “owns” the hardware
 - ✦ RAM
 - ✦ CPU

Multiple processes can run

- ✦ Everyone thinks he is the only one
- ✦ Like Kanye West

**I AM THE NUMBER ONE
HUMAN BEING IN MUSIC.
THAT MEANS ANY PERSON
THAT'S LIVING OR BREATHING
IS NUMBER TWO.**

- KANYE WEST

OS Basics: Process and Memory

Processes can address:

- ★ **4 GB of memory** in 32bit OS
 - ★ (2-3 GB actually)
- ★ Independent on how much memory (RAM) there really is

What if we have:

- ★ Only 2 GB RAM?
 - ★ OOM (Out Of Memory) when too much memory is used
- ★ 8 GB RAM?
 - ★ 2 Processes can use all their 4GB!

OS Basics – Kernelspace/Userspace

OS/CPU manages mapping between physical pages and process (virtual) pages – called **paging**

Why 4 GB?

- ★ 32 bit register size in Intel CPU
- ★ Register are used to address memory
- ★ $2^{32} = 4 \text{ billion} = 4 \text{ gigabyte}$

A process has therefore access to **4 billion one-byte** memory locations

OS Overview

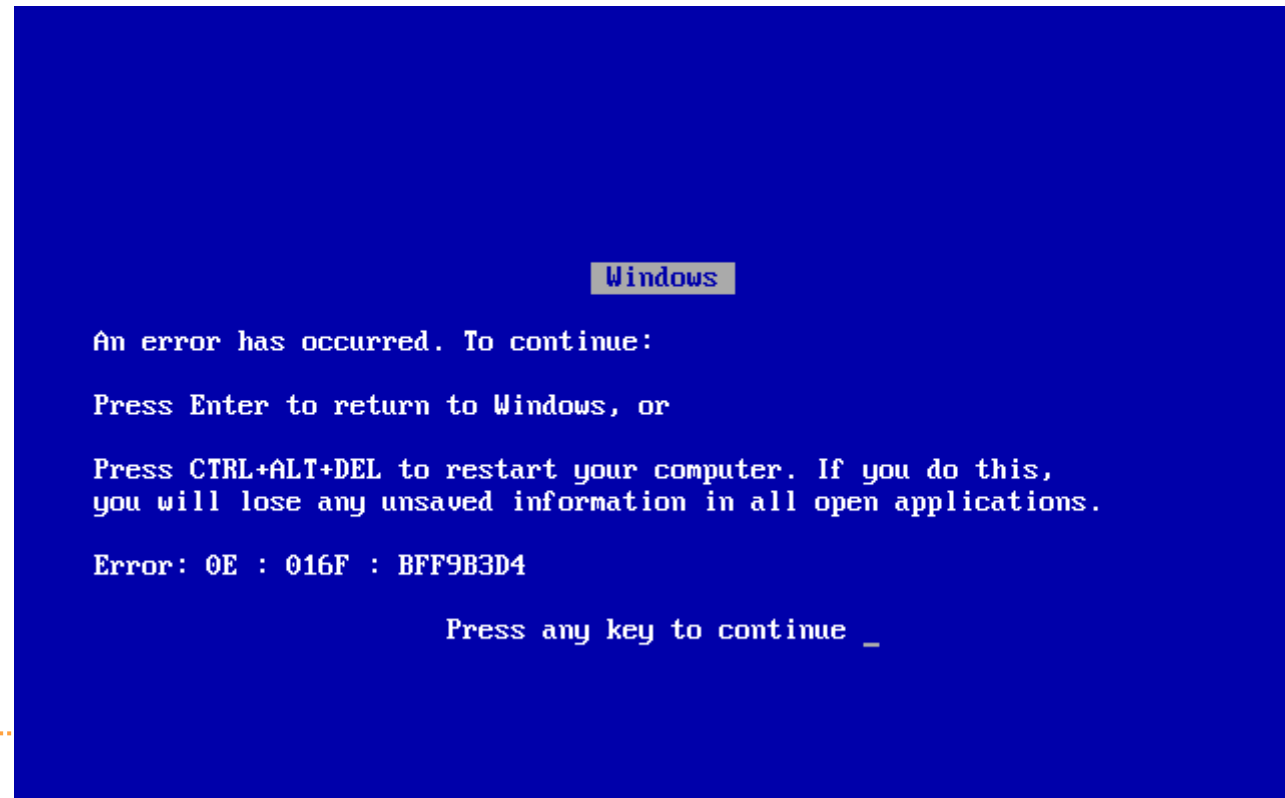

<http://www.slideshare.net/saumilshah/operating-systems-a-primer>

OS Overview

History lesson: “The good old times”

- ✦ Windows did not have true protected memory until windows NT/2000
 - ✦ Including all of DOS, Windows 3.1, Windows 95, 98, ME
- ✦ Every process could write into all other processes, or even the OS
- ✦ “Blue screen of death”

There's only one CPU, how can:

- ✦ Multiple programs run at the same time?
- ✦ The OS and the programs run at the same time?

Solution: Interrupts

- ✦ Timer interrupts
- ✦ Interrupts are handled by the kernel
 - ✦ Time / clock
 - ✦ Network interface
 - ✦ USB devices
- ✦ Kernel schedules the different processes

Recap:

- ✦ Processes are programs which are alive in the RAM
- ✦ Every process thinks he owns the computer (including all the RAM)
- ✦ Every process has access to 2^{32} (~4 billion) memory locations of 1 byte size

32 bit vs 64 bit

*This chapter may expect some know-how from later chapters
its more like a reference*

32bit vs 64bit

From 32 to 64 bit

- ★ You all are probably too young for this
- ★ But it was kinda big thing
- ★ AMD invented the current 64 bit architecture
 - ★ Intel wanted a new one: Itanium. Failed hard.
 - ★ (AMD was better than Intel in many respects back then. Sigh).
- ★ x86 to x64/amd64
 - ★ 8086, 80286, 80386, 80486, 80586 aka Pentium
- ★ “Is windows 64 bit twice as good/fast than windows 32 bit?”
 - ★ Width of the CPU registers define the amount of addressable memory

32bit vs 64bit

64 bit pros:

- ★ Can address more than 4 gb of memory per computer
 - ★ 18'446'744'073'709'551'616 bytes theoretically
- ★ 64 bit calculations are maybe a bit faster

64 bit cons:

- ★ Programs use more space
 - ★ Because pointers and data-types (integer) are twice as big
 - ★ On disk, memory and most importantly: cache

32bit vs 64bit

64 bit registers are prefixed with “R” (RAX, RIP, ...)

New registers: R8-R15

Pointers are 64 bit

Push/Pop are 64 bit

32bit vs 64bit

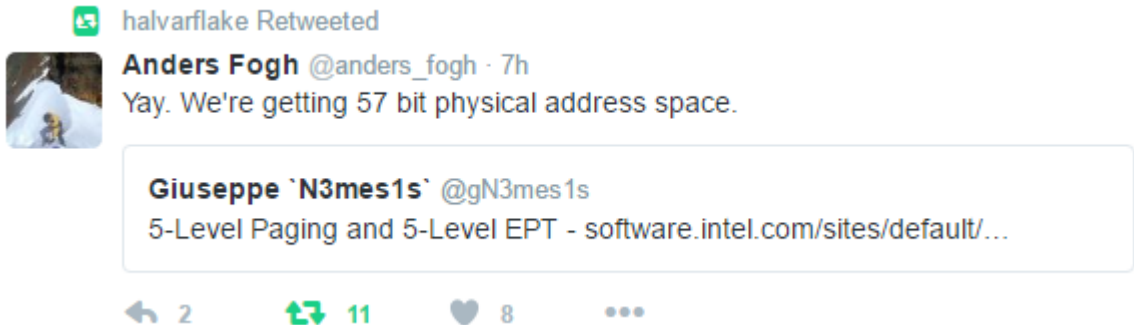

For 64 bit:

- ✦ 64 bit are 18 exabytes
- ✦ Only 47 bit are used (=140 terabytes)
- ✦ $< 0x00007fffffffffffff$

32bit vs 64bit

For 64 bit:

- ✦ 64 bit are 18 exabytes
- ✦ Only 47 bit are used (=140 terabytes)

32bit vs 64bit

Linux (and Windows) can execute 32 bit processes on a 64 bit OS

- ✦ C:\Program Files
- ✦ C:\Program Files (x86)

- ✦ /lib/lib
- ✦ /lib/lib64

The 32 bit process does not realize he's on a 64 bit system

- ✦ But needs a 32 bit runtime

For this presentation:

32 bit is “old” and “dead”

- ★ But its much easier to create and explain exploits in it

Old plan was: “Lets be modern, 64 bit only”

Current plan: “Lets be modern, but still use 32 bit to exploit stuff”

Sorry...

32bit vs 64bit

Recap

- ✦ There are some differences between 32 and 64 bit
- ✦ A 32 bit process can run on a 64 bit system as 32 bit

Excursion: C64

Commodore 64

~1 MHz, 64kb RAM (2^{16})

3 general purpose registers, 8 bit: A, X, Y

Stack Pointer: 8 bit, IP: 16 bit

Screen memory mapping: 0x0400 (1000 bytes, 40x25)
